SOME ARACHNIDA FROM NORTH CAROLINA.

BY NATHAN BANKS.

The material upon which this article is based was collected by Prof. J. H. Emerton, Mr. William Beutenmüller, and the writer, mostly in the mountainous, western part of the State. Prof. Emerton, during a collecting trip in the South in 1903, stopped at a number of localities in North Carolina. His itinerary was about as follows:

Durham, 8 and 9 July; Chapel Hill, 10 July; Salisbury, 12 July; Morganton, 12 July; Pineola, 14 July; Road to Roan Mt., 15 July; Roan Mt. Summit, 15 to 18 July; Linville, 19 July; Blowing Rock, 19 July; Paint Rock, 20 July; Asheville, 23 July; Balsam, 24 July; and Black Mt., Aug. 1 to 3.

Mr. Beutenmüller collected for several seasons in the valley of the Black Mountains for the American Museum of Natural History. The spiders were sent to me for identification. The writer spent the last two weeks of May, 1910, in the same valley visited by Mr. Beutenmüller. This valley is on the north fork of the Swannanoa River, about five miles from Black Mountain Station. The altitude is about 2,500 or 2,600 feet; and most of the collecting was done below 3,000 feet. Some specimens were taken on the summit of Mt. Graybeard, a neighboring peak, 5,548 feet high.

The spider fauna of these western mountains is similar in many respects to that found in New York and New England. Some few species, such as *Hypochilus* and *Nemastoma*, indicate the remnants of a fauna once connected with that of the Northwestern United States and China, or Mongolia. Why these few forms, so long resident in these mountain valleys, have failed to spread, will, doubtless, long be a puzzling question. There is apparently nothing in their habits to justify such a restricted habitat.

Swannanoa Vallev.

Callilepis femoralis n. sp. Pl. XXXV, fig. 11.

Cephalothorax pale red-brown, margin darker; mandibles redbrown; sternum and coxæ pale vellowish-brown; abdomen deep black; legs pale, but femora and tibiæ I and II black, and densely blackhaired. Eyes about as in C. imbecilla, the rows very short, and the S. E. perhaps a little larger than in C. imbecilla; sternum a little longer than broad; abdomen truncate at base, depressed; legs long and slender, the metatarsi and tarsi longer than usual in the genus; tibia I and II with three pairs of spines below, the last apical, two pairs below these metatarsi, tarsus I only a little shorter than metatarsus I.

Length 10 mm.

From Mt. Graybeard, N. Car., 23 May, 1910. Differs from C. imbecilla in longer legs, and darker femora and tibiæ I and II.

Callilepis imbecilla Keys.

Gayenna saltabunda Htz.

Durham.

Micaria agilis Bks.

Chapel Hill, road to Roan Mt., Pineola.

Scotinella n. gen.

Clubionid, maxillæ rather short, inclined over the lip, lip broader than long, eyes similar to *Liocranum*, posterior eye-row straight, the P. M. E. slightly elliptical, dorsal groove present; spinnerets short; legs slender, without spines, except two on anterior femora, and a double series of long ones beneath tibiæ and metatarsi I and II, no spines on hind legs; claws long, not much curved, with small teeth near base. Differs from *Scotina*, *Liocrannum*, *Agraca*, and *Apostenus* in absence of spines on the hind legs.

Scotinella pallida n. sp. Pl. XXXIV, fig. 7.

Cephalothorax uniform yellowish, sternum and legs paler; abdomen whitish; all clothed with short hairs, dense on abdomen, sparse on

cephalothorax. Cephalothorax a little longer than broad, broad in front, groove distinct; eyes as figured, mandibles moderately stout, each with a prominent erect bristle on middle of front; abdomen truncate at base, rather slender, sternum nearly as long as broad, broadest behind coxe II, somewhat 7-sided, rounded at tip. Legs slender, with short hairs, spines only as follows: two long, erect ones on middle of femur I, a double row of six each under tibia I, a double row under metatarsus I, 4 on inner side, 3 on outer side; beneath tibia II, 5 pairs, and under metatarsus II, 3 pairs, none of these are apical, and all very long.

Last joint of palpus densely clothed with short spine-like bristles. Length $2.3~\mathrm{mm}$.

From Black Mt., north fork of the Swannanoa River, May, under dead leaves in forest.

Dictyna sublata Htz.

Morganton, Durham.

Dictyna armata n. sp. Pl. XXXIV, fig. 9.

Male; cephalothorax reddish-brown, rather paler on the head, with white hairs; abdomen reddish-brown through the middle of dorsum, blackish on base and sides, the posterior dorsum often broken up by blackish bands, sometimes dorsum mostly all dark, with a pair of pale spots in front, one on each side before middle, and a row of pale spots behind in middle; legs very pale; venter and sternum pale. Female, cephalothorax pale yellowish through the middle, sides brownish, almost black on lower sides of head; abdomen pale yellowish, a faint dark spear-mark on base, two rows of brown spots behind, and the sides with dark marks; venter and sternum wholly pale, unmarked; legs very pale, and very slender, the abdomen rather short, broad, and flat. The male palpus has a very long tibial spur, which is faintly bifid at tip, and bears two bristles.

Length \circlearrowleft 1.5 mm.; \circlearrowleft 1.4 mm.

From north fork Swannanoa River, Black Mountain, N. Car.; the webs were found in dead, curled Rhododendron leaves lying on the ground.

Durham, Road to Roan Mt., Balsam, Swannanoa Valley.

Theridium atramontanum n. sp. Pl. XXXV, fig. 12.

Cephalothorax yellowish, with a brown median stripe from eyes to tip, sometimes broken up near eyes. Legs yellowish (\circlearrowleft) , in $\$ whitish with the femora I yellowish near tip. Abdomen grayishwhite, reticulate above, with a basal, median brown mark, one on each lower anterior side, and two rows of three or four dark spots on the posterior middle of the dorsum, sometimes these dark marks outline a pale median stripe; venter and sternum pale unmarked.

Of the general structure and shape of *T. differens*, the male abdomen rather low, the female Epeira-shaped. Legs long and slender.

Length $\cap{?}$, 2 to 2.5 mm.; $\cap{?}$, 2 to 2.3 mm., femora I ($\cap{?}$), 2 mm.; tibia plus patella, 2.1 mm.; metatarsus, 1.9 mm.

From north fork Swannanoa River, Black Mountain, N. Car.; usually found under the leaves of the lowland Rhododendrons.

Epesinus amœnus n. sp. Pl. XXXV, figs. 13, 15.

Cephalothorax pale, with a broad dark stripe over head and back to near the tip, a more or less distinct dark streak near or on the sides, eyes surrounded by black. Dorsum of abdomen grayish or blackish as far back as the humps, the sides and hind margin of this dark is edged with white; behind paler, but darker again toward tip; venter blackish on the sides, pale in the middle; sternum dark, with a pale median streak. Legs pale, broadly marked with brown, or reddishbrown; femur I mostly brown, others near tip; patellæ mostly dark; tibiæ brown at each end, broader at tip, and hardly distinct on legs II and III; metatarsi narrowly marked with brown at base and tip; and the tips of the tarsi usually darker. The cephalothorax is broad and rounded, the head distinctly elevated, the eyes as usual, but the hind row is scarcely recurved; the abdomen is flat, truncate at base, widened to the humps at the posterior third, and then tapers to tip.

Length 3 mm.

From north fork Swannanoa River, Black Mountain, N. Car., May; obtained by beating Rhododendron bushes.

Black Mts., Sept. (Beutenmüller), one male.

Diplocephalus carolinus n. sp. Pl. XXXIV, fig. 2.

Cephalothorax chestnut-brown; legs yellow-brown; abdomen black, sternum yellowish-brown, black on margins. Head elevated, into a median lobe, which is truncate in front and bears the P. M. E., which are over two diameters apart; A. M. E. small, scarcely diameter apart, farther from the larger A. S. E., the P. S. E. close to A. S. E. Inner edge of front of the mandibles with two small teeth; sternum fully as broad in front as long, rather rounded between hind coxe, which are separated by more than their width.

Length 1.5 mm.

From Black Mt., N. Car., Swannanoa Valley, sifting fallen leaves.

Gonglydium atramontensis n. sp. Pl. XXXIV, figs. 5, 8.

Cephalothorax pale yellowish, legs still paler; abdomen blackish above and below; sternum blackish. Cephalothorax broad, mandibles with three teeth on outer side and a large median one on the inner edge; palpi long and slender, the basal hook large, a sharp, straight, simple stylet at tip; the sternum as broad at base as long, triangular, sharp-pointed behind; legs long and slender.

Length 1.1 mm.

Cephalothorax whitish, with several short brown streaks in eyeregion, one each side on clypeus, and three brown spots on each side of the cephalothorax. Legs yellowish or brownish-yellow, the femora whitish, femora I and II with a broad brown stripe on anterior side beneath, behind mostly brown; femora III and IV with a dark brown stripe on the anterior side beneath, one behind and a less distinct one above, rest of legs not plainly striped, although tibiae III and IV are darker in front below than elsewhere. Abdomen white, with a pattern of rich brown marks as in the figure; venter and sternum whitish. Cephalothorax moderately broad; eyes all small and wide apart; legs II a little longer than I, femora II longer than the cephalothorax, tibiae and metatarsi I and II each with two pairs of long spines beneath, the second pair at the middle of joint; femur I with three bristles on front, and two above.

Length 3.5 mm.

LYCOSIDÆ.

Pardosa retrorsa n. sp. Pl. XXXIV, figs. 3, 6.

Cephalothorax nearly black on the sides, black on eye-region, and there traversed by a narrow median line of white hair, extending down to the front eye-row; behind with a broad median reddish stripe, much constricted before the dorsal groove; some pale spots on the sides; and some white on the sides of clypeus. Mandibles reddish-brown, maxillæ pale, lip black, sternum blackish; abdomen pale above, blackish on anterior sides, and with some scattered black marks above, most noticeable behind; venter pale. Legs pale, the front femora black, and other femora and hind tibiæ more or less distinctly banded with dark; basal joint of palpus black, rest pale. Of general shape of *P. lapidicina*, but legs perhaps a little longer, all with long stout spines.

Length 6 mm.; hind legs 15 mm.

From Linville, N. Car., July (Emerton). Related to *P. lapidicina*, but the palpus quite different, and the white line on eye-region is peculiar. A female, apparently of this species, sent by Prof. Emerton, was taken at Coles Creek Notch, 20 miles north of Bloomsburg, Pa., 19 Sept., by Mr. Lutz.
